Chemistry Cheatsheet

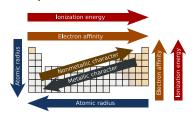

Noa Sendlhofer & Christian Leser nsendlhofer & cleser

partly based on the work by L. Hoffmann & D. Vermee Ihoffma & dvermee

- Energy: $1eV = 1.602 \cdot 10^{-19} J$, 1cal = 4.18J
- Pressure: $1Pa=9.892atm=1.0 \cdot 10^{-5}bar=7.5 \cdot 10^{-3}torr$
- Amount of substance: $1 \text{mol} = 6.022 \cdot 10^{23}$ elementary entities (Avogadro constant)
- Length: $1\text{Å} = 10^{-10} m$
- STP thermodynamics: 25C = 298K, 1bar, 1mol, 1 cal
- STP electrochemistry: 25C = 298K, 1atm, concentration 1M

- Kinetic energy: $E_{kin} = \frac{1}{2} \cdot m \cdot v^2$
- Potential energy: $E_{pot} = m \cdot g \cdot \Delta h$
- electrostatic: $E_{el} = \frac{\kappa Q_1 Q_2}{13}$ $\kappa = \frac{1}{4\pi\epsilon_0}$
- Photon energy: $E_{\gamma} = h \cdot f = \frac{h \cdot c}{\lambda}$
- De Broglie wavelength: $\lambda = \frac{h}{m \cdot v}$
- Specific heat capacity: $C_s = \frac{q}{m \Lambda T}$

- Ionisation energy: The ionization energy is the quantity of energy that an isolated, gaseous atom in the ground electronic state must absorb to discharge an electron, resulting in a cation
- Electron affinity: Electron affinity is defined as the change in energy (in kJ/mole) of a neutral atom (in the gaseous phase) when an electron is added to the atom to form a negative
- Electronnegativity: Electronegativity is a measure of an atom's ability to attract shared electrons to itself.

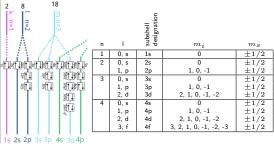

- Atomic number = #protons = #electrons
- mass number = #protons + #neutrons

Heisenbergs uncertainty principle $\Delta x \cdot \Delta p \geq \frac{h}{4 \cdot \pi}$ Due to duality of electrons (acting like waves and elementary entities at the same time), impossible to exactly describe position and momentum si-

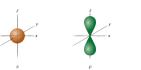

Effective nuclear charge (approx.): $Z_{eff} = Z - S$

$$Z=\# {
m protons},\, S=\# e^-$$
 on all full shells

In periodic table: Z_{eff} increases from left to right ightarrow electrons are more attracted and hence atomic radius is smaller, the further right in the periodic table.

- **n**: principal quantum number \rightarrow size of orbital
- I: angular quantum number → shape of orbital
- ullet m_l : magnetic quantum number o orientation of orbital
- m_a: spin quantum number

Pauli Exclusion: Each electron has unique set of quantum numbers Hund's rule: Every orbital in sublevel is first singly occupied

3. Chemical bondings

Two atoms share electron pairs octet rule: Atom tries to acquire noble state (2 valence electrons for H and He, 8 valence electrons for all other) exceptions:

- · Odd electrons
- Less / more than 8 VE's on central atom

- Write symbols and connect with single bonds
- · Complete ocets around non-central atoms
- Place remaining VE around central atom
- Try multiple bonds if central atom does not have octet
- if multiple lewis structures possible: choose most stable according to formal charge

Electrons transfered from atoms with lower EN to atoms with higher EN \rightarrow cations (+) (smaller radius) and anions (-) (bigger radius). electrostatic attraction. $\Delta EN > 1.7 \rightarrow$ ionic bonding lattice energy ΔU : Energy required to separate ions to infinite

cores form grid structure, electron et cloud (reason for electricity and heat conduction) surrounds atomic cores

 $\Delta EN > 0.5$: polar bonding, density of e^- higher at δ^- atom. If molecular structure leads to → dipole moment

results if new bondings are formed to satisfy octet rule, ignores electronegativity

Determine formal charge in Molecule:

- split all bondings in middle
- ullet atoms formal charge = VE if unpaired $-e^-$ of that atom after splitting bondings
- effective charge of molecule = sum of formal charges

length:
$$\equiv <=<-$$
 strength: $-<=<\equiv$

Most stable molecule:

- least formal charges.
- if formal charges necessary: option with the smallest effective charge of molecule
- negative formal charge on electronegative atom

4. Molecular models

structural

	Pair Geometry					
Electron Dense Areas		No Lone Pairs	1 Ione Pair	2 Ione Pairs	3 Ione Pairs	
2	Linear 180°	Linear				
3	Trigonal planar	Trigonal planar	Bent			
4	Tetrahedral	Tetrahedral	Trigonal pyramidal	Bent		
5	Trigonal bipyramidal 120°/90°	Trigonal bipyramidal	Seesaw	T-shaped	Linear	
**	Octahedral 90°	Octahedral	Square pyramidal	Square planar		

5. State of matter

- 1. Van-der-Waals interactions (weak)
 - (a) Dipol-Dipol

Sum of all dipole moments from polar bonds in molecule. (molecular dipole) ($\Delta EN > 0.5$)

(b) Dispersion

Temporary fluctuations of the electrons can cause an induced dipole. These forces always exist. Force increases with molecule size and also affected by molecular shape.

2. Ion-Dipole Interactions (strong)

Very important for solutions. Ions solvated by polar liquid.

3. Hydrogen bonding (strong)

One type of dipole-dipole interaction. N, O, F are very electronegativ \Rightarrow very polar bonds with H.

Ion-Dipole H-Bonding > Dipole-Dipole \approx > 50kJ/mol $\sim 25 kJ/mol$ Dispersion $\sim 50 kJ/s$

Colligative Properties: Changes depend on amount of solute added, but not which solute.

 $\Delta T_b = T_b(\text{solution}) - T_b(\text{solvent}) = iK_b m$

m = molality of solute

 $K_b = \text{molal bp elevation constant}$

i = van't Hoff factor

- =1 for non-electrolytes
- = Number of ions produced for electrolytes. e.g 2 for NaCl

$$P_{\rm vap}^{\rm sol} = X_{\rm solvent} * P_{\rm vap}^{\rm pure}$$

Raoult's law - Solution is an ideal solution. All intermolecular interactions are identical.

$$\Delta T_f = T_f(solution) - T_f(solvent) = -iK_f m$$
 $m =$ molality of solute

 $K_f = \text{molal fp depression constant}$

i = van't Hoff factor

• X Mole fraction = $\frac{\text{moles solute}}{\text{total moles}}$

- M Molarity = $\frac{\text{moles solute}}{\text{litres solution}}$
- m Molality = $\frac{\text{moles solute}}{\text{kg solvent}}$
- Mass% = $\frac{\text{mas solute}}{\text{total mass}} \cdot 10^2$, ppm: $\cdot 10^6$, ppb: $\cdot 10^9$

- Assumptions of IGL
 - Gas molecules don't occupy much of total volume.
- Gas molecules don't interact.
- Ideal Gas Law: pV = nRT = NkT
- $p[Pa], V[m^3], n[\text{num of moles}], R[\frac{J}{mol*K}], T[K]$
- Density $\rho = M \frac{n}{V} = M \frac{p}{PT}$

$$p_i = n_i \cdot \frac{RT}{V}$$
 total pressure $= \sum$ of all partial pressures.

Pressure needed to counteract osmotic flow.

$$\Pi = i \left(\frac{n}{V}\right) RT = iMRT$$

6. Thermodynamics

- Open Can echange matter and energy w/ surrounding
- Closed Can echange energy w/ surrounding
- Isolated Nothing can be exchanged

- $\Delta E = E_{\text{final}} E_{\text{initial}}$ $\Delta E>0$ system gained energy $\Delta E < 0$ system lost energy
- 1st Law of Thermodynamics
- $\Delta E = q + w$ q = heat added to system, w = work done on system

 ΔH tells us about heat transferred during chemical reaction.

- ullet $\Delta H = q_p$ heat flow at constant P • $-P\Delta V = \text{pressure-volume work}$
- $\Delta H > 0 \Rightarrow$ endothermic
- $\Delta H < 0 \Rightarrow {\rm exothermic}$

Heat flow required to raise substance's T by 1 degree ${}^{\circ}C$ (or K)

$$C_m = ext{molar heat capacity} = \left[rac{J}{mol * ^{\circ} ext{C}}
ight] = \left[rac{J}{mol * K}
ight]$$
 $C_s = ext{specific heat capacity} = \left[rac{J}{g * ^{\circ} ext{C}}
ight] = \left[rac{J}{g * K}
ight]$

$$q = n * C_{\mathsf{m/s}} * \Delta T$$

Hess's Law: $\Delta H_{\rm rxn} = \sum \Delta H_{\rm c}$ e.g Enthalpies of Formation: ΔH_f^c

Entropy is a measure of disorder in a system. All spontaneous processes are irreversible. S is a state function. • $\Delta S = \frac{q_{\text{rev}}}{T}$, $q_{\text{rev}} = \text{heat flow for reversible process}$

- $S = k_b * ln(W)$, $k_b = Boltzmann's constant$, W = num
- of microstates

$\Delta S > 0$: increasing microstates e.g increasing V, increasing T, increasing n, increasing complexity

of molecules, melting solids, vaporizing liquids

Entropy of the universe increases for any spontaneous process.

$$\Delta S_{
m univ} = \Delta S_{
m sys} + \Delta S_{
m surr} > 0$$
 (spontaneous, irreversible) $\Delta S_{
m univ} = \Delta S_{
m sys} + \Delta S_{
m surr} < 0$ (nonspontaneous)

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} < 0$$
 (nonspontaneou $\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0$ (reversible)

$$\Delta S_{\text{univ}} = \Delta S_{\text{sys}} + \Delta S_{\text{surr}} = 0$$
 (reversible

$$G = H_{\rm sys} - TS_{\rm sys}$$
 at constant T

ΔH	ΔS	$-T\Delta S$	ΔG	Reaction Characteristics
-	+	-	-	at all T Spontaneous
+	-	+	+	at all T Nonspontaneous
-	-	+	+or-	↓T Spon.; ↑T Nonspon.
+	+	-	+or-	↓T Nonspon.; ↑T Spon.

Given general rxn: $\alpha A + \beta B \longrightarrow \gamma C + \delta D$

$$0 < \mathsf{Rate} = \underbrace{-\frac{1}{\alpha}\frac{d[A]}{dt} = -\frac{1}{\beta}\frac{d[B]}{dt}}_{\mathsf{Rate}} = \underbrace{\frac{1}{\gamma}\frac{d[C]}{dt} = \frac{1}{\delta}\frac{d[D]}{dt}}_{\mathsf{Rate} \ \mathsf{of} \ \mathsf{reactants}}$$

$$\boxed{\mathsf{Rate}[\frac{M}{s}] = k[A]^m[B]^n}$$

- · rate only depends on reactants
- \bullet m, n are the reaction orders

ullet k is the rate constant

- m, n can be $0, \frac{1}{2}, 1, 2, ...$
- \bullet m+n is overall rxn order
- m, n are not necessarily equal to α, β

$$\begin{array}{l} \text{Consider } A \longrightarrow B \\ [A]_t = \text{concentration of } A \text{ at time } t \\ [A]_0 = \text{concentration of } A \text{ at time } t = 0 \\ \end{array}$$

1st Order

$$\mathsf{Rate} = -\frac{d[A]}{dt} = k[A]^1$$

$$ln[A]_t = -kt + ln[A]_0$$

$$[A]_t = [A]_0 exp(-kt)$$
 2nd Order

$${\it Rate}=-\frac{d[A]}{dt}=k[A]^2$$

$$\frac{1}{[A]_t}=kt+\frac{1}{[A]_0}$$
 Zero Order

$$\mathsf{Rate} = -\frac{d[A]}{dt} = k[A]^0 = k$$

$$[A]_t = -kt + [A]_0$$

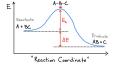

Time needed for $[A]_t = \frac{1}{2}[A]_0$

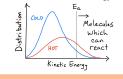

$$\underbrace{t_{\frac{1}{2}} = \frac{0.693}{k}}_{\text{1st Order}} \quad \underbrace{t_{\frac{1}{2}} = \frac{1}{k[A]_0}}_{\text{2nd Order}} \quad \underbrace{t_{\frac{1}{2}} = \frac{[A]_0}{2k}}_{\text{Zero Order}}$$

Reaction requires reactant molecules to collide with correct orientation and enough energy.

Higher T: reactants collide more often and with more kinetic E.

Molecules need minimum energy to react; Activation Energy, E_a

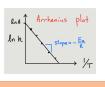

$$\begin{array}{l} \alpha A + \beta B + \gamma C \longrightarrow \text{products} \\ \mathsf{Rate} = k[A]^m[B]^n[C]^p \end{array}$$

$$k(T) = \underbrace{\left(\begin{array}{c} \text{collisions} \\ \text{per time} \end{array} \right) * \left(\begin{array}{c} \text{fraction of collisions} \\ \text{properly oriented} \end{array} \right)}_{A} * \underbrace{\left(\begin{array}{c} \text{fraction of molecules} \\ \text{with } E > E_{a} \end{array} \right)}_{* exp\left[\begin{array}{c} -E_{a} \\ RT \end{array} \right]}$$

A is a "frequency factor", assumed T-independent

$$ln(k) = \frac{-E_a}{R} \frac{1}{T} + ln(A)$$

A sequence of elementary rxns that sum to the overall rxn. The kinetics of elementary rxns are determined by how many molecules have to collide, referred to as the molecularity.

Elementary rxns have rate law where $m, n, p \dots$ are equal to stoichiometric coefficients. Molecularity Elementary rxn Rate law

Unimolecular	$A \longrightarrow P$	k[A]	
Bimolecular	$A + A \longrightarrow P$	$k[A]^2$	
Bimolecular	$A + B \longrightarrow P$	k[A][B]	
ep Reactions			

Overall rate law results from the individual rate laws for the indi-

vidual elementary reactions.

$$\underbrace{ \begin{array}{ccc} 2A & \xrightarrow{k_1} I + C \\ I + B & \xrightarrow{k_2} A + D \end{array}}_{ \ \, A + B & \longrightarrow C + D \ \, \big \} \text{ elementary rxns}$$
 Assume $k_1 << k_2$, i.e. step 1 is "rate limiting"

 \implies rate overall = $k_1[A]^2$

Substances that increase rxn rate, but are neither produced nor consumed in overall rxn.

$$\operatorname{Can} \left\{ \begin{array}{ll} \operatorname{increase} \mathsf{A} & \Rightarrow \operatorname{better} \operatorname{orient} \operatorname{molecules} \\ \operatorname{lower} \mathsf{A} & \Rightarrow \operatorname{lower} \operatorname{energy} \operatorname{of} \operatorname{transition} \operatorname{state} \operatorname{or} \\ \operatorname{allow} \operatorname{new} \operatorname{mechanism} \end{array} \right.$$
 Lower E_a has bigger impact

 \Rightarrow Appears in exponent of $k(T) = A * exp(\frac{-Ea}{PT})$

8. Chemical Equilibrium

$$A \xrightarrow[k_r]{k_T} B$$
, at equilibrium: Rate $= k_f[A] = k_r[B]$

molarity concentrations $\begin{array}{ccc} K_c = \frac{[C]^{\gamma}[D]^{\delta}}{[A]^{\alpha}[B]^{\beta}} & K_p = \frac{[P_C]^{\gamma}[P_D]^{\delta}}{[P_A]^{\alpha}[P_B]^{\beta}} = K_c(RT)^{\Delta n} \\ K >> 1 \rightarrow \text{products dominate}, \ K << 1 \rightarrow \text{reactants dominate} \end{array}$

K depends on T and is unitless heterogeneous equilibria: exclude pure solids / liquids from K reaction quotient Q if not at equilibrium, calculated like K_c

- rxn written in reverse: $K = K_{\text{original}}^{-1}$
- rxn multiplied by n: $K = (K_{\text{original}})^{i}$
- multistep rxn: $K = K_1 \cdot K_2 \cdot K_3 \dots$
- With catalysts: equilibrium is reached faster, K unchanged

Disturbance in concentration

system reacts to consume added substance Substance added

Disturbance in pressure

reduced volume \rightarrow system shifts in direction with fewer moles of

Evethermi

Disturbance in temperature

	Liluotileilille	LAUGHEITHIC	
increased T	right shift	left shift	
decreased T	left shift	right shift	

9. Acid Base Reactions

$$\underbrace{HA(aq)}_{\text{acid }(H^+\text{-donor})} + \underbrace{B(aq)}_{\text{base }(H^+\text{-acceptor})} \rightleftharpoons \underbrace{A^-(aq)}_{\text{conjugate base}} + \underbrace{HB^+(aq)}_{\text{conjugate acid}}$$
strong acids/bases completely ionize, weak acids/bases don't

Amphiprotic substances (ex. Water) can act as acid and base

$$\begin{split} \underbrace{H_2O(l)}_{\text{acid}} + \underbrace{H_2O(l)}_{\text{base}} &\rightleftharpoons \underbrace{OH^-(aq)}_{\text{conjugate base}} + \underbrace{H_3O^+(aq)}_{\text{conjugate acid}} \\ K_w &\equiv K_C = [OH^-][H_3O+] = 10^{-14}(25^{\circ}C) \end{split}$$

acid-dissociation $K_a \equiv K_C = \frac{[A^-][H_3O^+]}{[H_A]}$ $K_b \equiv K_C = \frac{[HB^+][OH^-]}{[B]}$

4 p-Scales
$$p(\xi) = -\log(\xi) \qquad pH = -\log[H_3O^+] \quad pOH = -\log[OH^-]$$

$$pH + pOH = 14$$
 $pH < 7 \rightarrow \text{acid}$ $pH > 7 \rightarrow \text{base}$

 $CH_3COOH + CH_3COONa \rightarrow \text{dissociates to } CH_3COO^-$

$$HA(aq) + OH^{-}(aq) \rightleftharpoons A^{-}(aq) + H_2O(l)$$

 $A^{-}(aq) + H_3O^{+}(aq) \rightleftharpoons HA(aq) + H_2O(l)$

$$[H_3O^+] = K_a \frac{[HA]}{[A^-]} \to pH_{\mathrm{buffer}} = pK_a + \log(\frac{[base]}{[acid]})$$
 For disturbance small relative to $[HA], [A^-] \to \mathrm{small}$ pH change

10. Redox Reactions

- Atoms in elemtal form: 0
- · Monoatmic ions: ionic charge • Nonmetals in ionic/molecular compounds:
- negative oxidation numbers Oxygen: -2 (except peroxide ion, O_2^2 -, -1)
- (except if bonded to metal, -1)
- (always) (except if bonded to oxygen)
- Sum of oxidation numbers for atoms in compound equals its

- Anode(-): where oxidation occurs
- Cathode(+): where reduction occurs
- · Anions migrate towards anode. Cations migrate towards

Electric potential = potential energy difference per unit charge

$$1V = \frac{1.6 * 10^{-}19J}{1.6 * 10^{-}19C}$$

 $E_{\rm cell}^{\circ} \equiv \text{Cell voltage at standard conditions}$ $E_{\rm red}^{\circ} \equiv \text{Potential energy available if reduced}$

transferred in balanced cell rxn

Cell potential $\Rightarrow E_{\text{cell}}^{\circ} = E_{\text{red}}^{\circ}(\text{cathode}) - E_{\text{red}}^{\circ}(\text{anode})$

$$\Delta G^{\circ} = \text{J/mol of rxn}$$

$$\Delta G^{\circ} = -nFE_{\text{cell}}^{\circ}$$

$$F = \text{Faraday's constant}$$

$$= 96'485\text{C/mol }e^{-}\text{'s}$$

$$E_{\text{cell}}^{\circ} > 0, \Delta G^{\circ} < 0$$

$$\Rightarrow \text{Spontaneous!}$$

$$n = \text{unitless number moles of }e^{-}\text{'s}$$
